## ABSTRACT

This computer program computes a ballistic trajectory from burn out or any point thereafter to impact. It assumes point mass and a spherical earth. The program takes into account air resistance, the variation of the gravitational and centrifugal field with altitude, and earth's rotation. It uses a system of co-ordinates (X, Y, and Z) rigidly connected with the rotating earth.

The computer program is written in FORTRAN II and an autocoder deck has been compiled. The program is run on the IBM 1410 computer. It is being adapted for use on the IBM 1620 computer for use by the Army. This program may be obtained from the Scientific Programming Section; Program No. SP9. It was programmed by W. B. Warren of the Scientific Research Staff.

Approved By:

  
Harry C. Crews, Jr.  
Director, Special Projects Office

## SYMBOLS

<u>Symbol</u>	<u>Computer Symbol</u>	
$\beta$	BETA	Bearing angle - Clockwise horizontal angle from north to direction of flight
$\delta$	DELTA	Flight path angle - Angle between missile axis and local horizontal. Angle is positive when missile is climbing.
$\phi$	PHI	Latitude - Positive in northern hemisphere, negative in southern
$\theta$	THE TA	Longitude - Increases to the east. When firing east, $\theta_0 = 0$ , to the west, $\theta_0 = \pi/2$
X	X	See Figure 1 - Co-ordinate system with center of earth as origin. Z is the polar axis. X and Y are in the plane of the Equator and are $90^\circ$ apart. The X axis corresponds to the point where $\theta = 0$ . All are positive as shown.
Y	Y	
Z	Z	
$\gamma$	GAMMA	Range angle - Vertex at center of earth measured from the point where data were put into the program to the position attained along the trajectory.
$A_x$	AX	Acceleration in the X direction
$A_y$	AY	Acceleration in the Y direction
$A_z$	AZ	Acceleration in the Z direction
$A_t$	AT	Acceleration along the trajectory
$V_x$	VX	Velocity in the X direction
$V_y$	VY	Velocity in the Y direction
$V_z$	VZ	Velocity in the Z direction
$V_t$	VT	Velocity along the trajectory
$R_a$	RA	Distance from center of earth to re-entry body

Symbols (Cont.)

<u>Symbol</u>	<u>Computer Symbol</u>	
H	ALT	Distance from surface of earth to re-entry body
R	R	Radius of earth - Constant (20,902,890 ft.)
$\bar{r}$	-	Geocentric location vector
$g_o$	GO	Acceleration of gravity at sea level - constant (32.174 ft/sec <sup>2</sup> )
g	GRAV	Acceleration of gravity at altitude
U	U	Earth's rotation in radians per second - constant ( $2\pi/24 \times 3600$ )
$\sigma$	SIGMA	Angle of a spherical triangle - see Figure 3
u	AMU	$(g_o R^2)^{\frac{1}{2}}$
$(\frac{w}{C_D A})$	BALCO	Ballistic coefficient - Estimated from shape and dimensions
$\rho$	DEN	Air density from tape for IBM 1410 program - computed internally in IBM 1620 program

PHYSICAL CONSTANTS

$$R = 20,902,890 \text{ feet}$$

$$g_o = 32.174 \text{ ft/sec}^2$$

$$U = 2\pi/24 \times 3600 \text{ radians/sec.}$$

$$u^2 = g_o R^2$$

## INTRODUCTION

This computer program may be used to study the free flight and re-entry portions of a ballistic trajectory. The information calculated and printed by the computer includes time of flight, location in both X, Y, and Z from earth's center and latitude, longitude and altitude from earth's surface, acceleration, velocity, flight path angle, bearing angle and range in nautical miles.

The model chosen for use in this computer program was taken from References 1 and 2. Point mass and a spherical earth are assumed. The basic acceleration equations are developed in Reference 1. Reference 2 discusses a similar computer program which uses the same acceleration equations and many of the other relationships used in this computer program.

A portion of the computer program discussed in Reference 3 was used to compute density in the IBM 1620 Computer program. This portion is an integral part of that program.

### Library Functions Used:

SQRT  
SIN  
COS  
EXP  
ATAN

## ANALYSIS

### Initial Conditions

The computer program will accept initial conditions at burn out or at any time thereafter until impact. The items of information needed are punched on two IBM cards which are placed at the end of the deck.

<u>Items</u>	<u>Comments</u>
$\delta$	Positive when missile is climbing.
$\beta$	Clockwise horizontal angle from north
$\theta$	Initial $\theta_0 = 0$ when flying eastward and $\theta_0 = \pi/2$ when flying toward the west
$\phi$	Positive in northern hemisphere
H	Altitude above earth's surface
R	20,902,890 ft. (earth's radius)
$V_t$	Velocity along the trajectory
$g_0$	32.174 ft/sec <sup>2</sup>
U	$2\pi/24 \times 3600$ radians per second
$(\frac{w}{C_D A})$	Ballistic coefficient

All angles are put into the computer in radians. The computer program is designed to accept and compute English units. All angles are printed in degrees. (Program SP-9-E)

The computer program may be modified to accept, compute and print metric units by using metric units for H, R,  $V_t$ ,  $g_0$  and by using conversion

factors for the altitude and density in the density subroutine in the IBM 1620 computer program. A deck in metric units has been prepared. (SP-9-M)

#### Development of Equations

In order to provide the proper initial conditions, the following set of co-ordinate transformations were used as an integral part of the computer program. (See Figure 1):

$$X = R_a \cos \phi \cos \theta \quad (1)$$

$$Y = R_a \cos \phi \sin \theta \quad (2)$$

$$Z = R_a \sin \phi \quad (3)$$

By definition:

$$H = R_a - R \quad (4)$$

It follows that:

$$R_a = (X^2 + Y^2 + Z^2)^{\frac{1}{2}} \quad (5)$$

In order to convert the input velocity along the trajectory to components in the X, Y, and Z directions, the angles  $\delta$ ,  $\beta$ ,  $\phi$ , and  $\theta$  are used. See Figure 1.  $\delta$  is the angle the vehicle makes with the local horizontal.

$$V_t \sin \delta = \text{a velocity component along } R_a \quad (6)$$

$$V_t \sin \delta \sin \phi = \text{a velocity component along the } Z \text{ axis} \quad (7)$$

$$V_t \sin \delta \cos \phi = \text{a velocity component along } R_a \text{ projected into the plane of the Equator} \quad (8)$$

$$V_t \sin \delta \cos \phi \sin \theta = \text{a velocity component along the } Y \text{ axis} \quad (9)$$

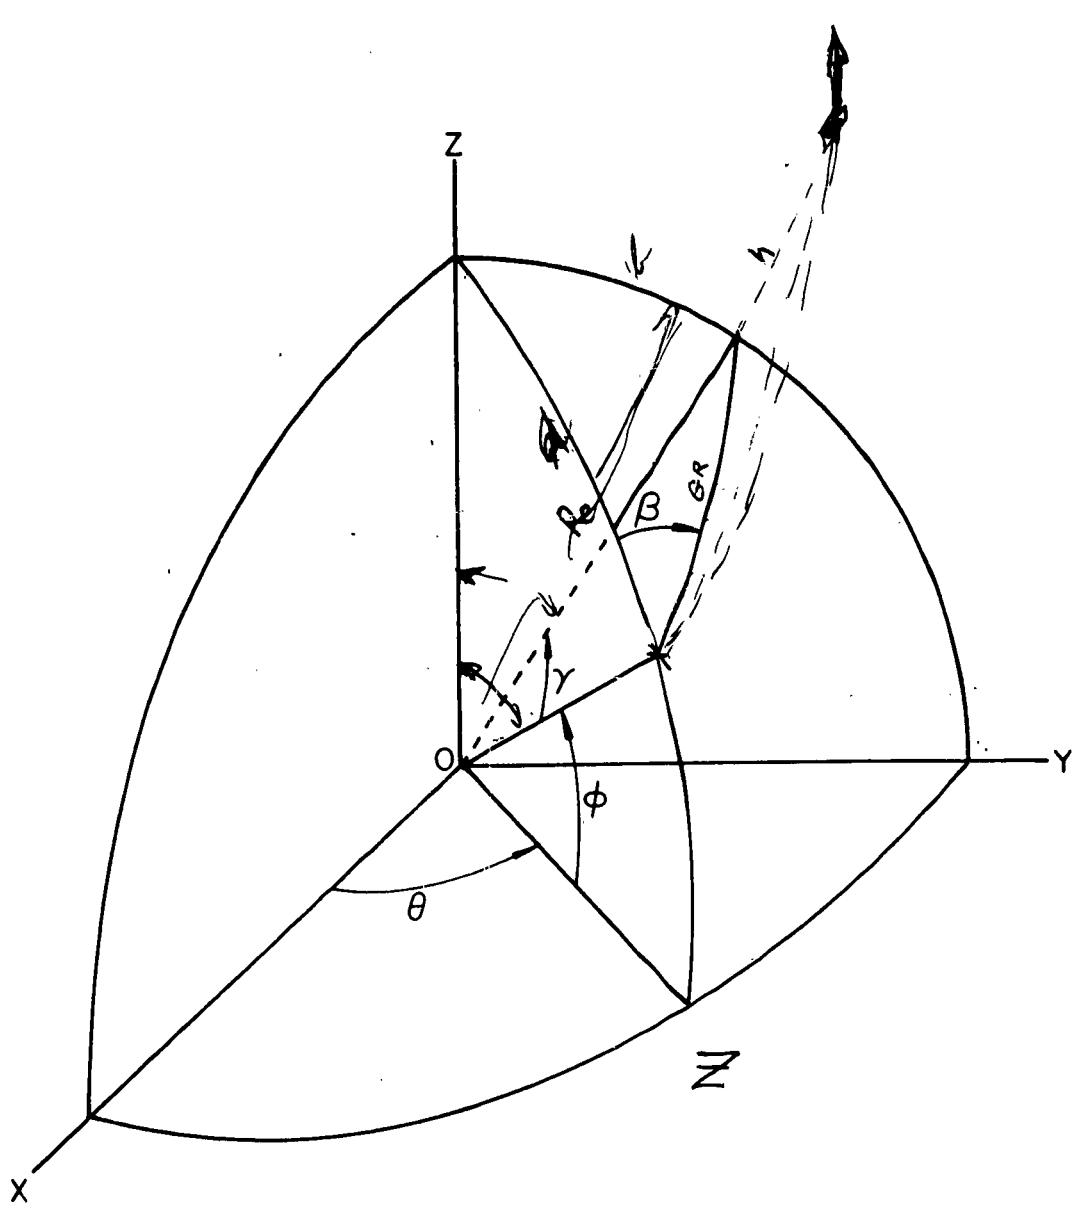

FIGURE 1

$$V_t \sin \delta \cos \phi \cos \theta = \text{a velocity component along the X axis} \quad (10)$$

$$V_t \cos \delta = \text{a velocity component parallel to the earth's surface} \quad (11)$$

$$V_t \cos \delta \sin \beta = \text{a velocity component along a parallel of latitude} \quad (12)$$

$$V_t \cos \delta \sin \beta \sin \theta = \text{a velocity component along the X axis} \quad (13)$$

$$V_t \cos \delta \sin \beta \cos \theta = \text{a velocity component along the Y axis} \quad (14)$$

$$V_t \cos \delta \cos \beta = \text{a velocity component along a meridian of longitude} \quad (15)$$

$$V_t \cos \delta \cos \beta \sin \phi = \text{a velocity component along } R_a \text{ projected into the plane of the Equator} \quad (16)$$

$$V_t \cos \delta \cos \beta \sin \phi \sin \theta = \text{a velocity component along the Y axis} \quad (17)$$

$$V_t \cos \delta \cos \beta \sin \phi \cos \theta = \text{a velocity component along the X axis} \quad (18)$$

$$V_t \cos \delta \cos \beta \cos \phi = \text{a velocity component along the Z axis} \quad (19)$$

The following three equations are integral parts of the computer program. The signs (+ or -) of the sin and cos functions of  $\delta$ ,  $\beta$ ,  $\phi$ , and  $\theta$  were analyzed as the angles changed. The proper sign was given to the components used.

Combining (10), (13), and (18):

$$V_x = V_t (\sin \delta \cos \phi \cos \theta - \cos \delta \sin \beta \sin \theta - \cos \delta \cos \beta \sin \phi \cos \theta) \quad (20)$$

Combining (9), (14), and (17):

$$V_y = V_t (\sin \delta \cos \phi \sin \theta + \cos \delta \sin \beta \cos \theta - \cos \delta \cos \beta \sin \phi \sin \theta) \quad (21)$$

Combining (7) and (19):

$$V_z = V_t (\sin \delta \sin \phi + \cos \delta \cos \beta \cos \phi) \quad (22)$$

The component velocities can be used to find the velocity along the trajectory.

$$V_t = (V_x^2 + V_y^2 + V_z^2)^{\frac{1}{2}} \quad (23)$$

If one takes into account the air resistance, the variation of the gravitational and centrifugal field and earth's rotation, the equation of motion for the ballistic vehicle becomes:

$$m \ddot{\bar{r}} = m \bar{g} + \bar{W} + \bar{k}_c + \bar{k}_n \quad (24)$$

where

$m$  = mass of vehicle

$\bar{r}$  = radius vector from center of earth to vehicle

$\bar{g}$  = acceleration due to gravity

$\bar{W}$  = air resistance

$\bar{k}_c$  = Coriolis force

$\bar{k}_n$  = centrifugal force

Examining equation (24) term by term, one obtains:

$$m \bar{g} = - \frac{m u^2}{R_a^2} \frac{\bar{r}}{R_a} \quad (25)$$

where

$$u^2 = g_o R^2$$

R = radius of earth

R<sub>a</sub> = distance from earth's center to vehicle

$$\bar{W} = - \bar{v}_c v^{n-1} \quad (26)$$

where c and n are factors which depend on air density, the shape of the vehicle and the velocity;

$$\bar{k}_c = 2m (\bar{v} \times \bar{U}) \quad (27)$$

where

$\bar{U}$  = angular velocity of the rotation of earth in radians per second

and

$$\bar{k}_n = m U^2 r \cos \phi = m U^2 (X^2 + Y^2)^{\frac{1}{2}} \quad (28)$$

In this analysis, the air resistance was assumed to be proportional to the square of velocity so that equation (26) becomes

$$\bar{W} = \frac{\bar{v} \rho g V m}{2 \left( \frac{w}{C_D A} \right)} \quad (29)$$

Writing equations (25) through (29) in component form, we obtain:

$$A_x = - \frac{u^2 X}{R_a^3} - \frac{\rho V t g V_x}{2 \left( \frac{w}{C_D A} \right)} + 2 V_y U + U^2 X \quad (30)$$

$$A_y = - \frac{u^2 Y}{R_a^3} - \frac{\rho V t g V_y}{2 \left( \frac{w}{C_D A} \right)} - 2 V_x U + U^2 Y \quad (31)$$

$$A_z = -\frac{u^2 Z}{R_a^3} - \frac{\rho V_t g V_z}{2 \left( \frac{w}{C_D A} \right)} \quad (32)$$

Integrating these equations in computer form, we obtain

$$V_{x_n} = V_{x(n-1)} + A_x \Delta t \quad (33)$$

$$V_{y_n} = V_{y(n-1)} + A_y \Delta t \quad (34)$$

$$V_{z_n} = V_{z(n-1)} + A_z \Delta t \quad (35)$$

$$X_n = X_{n-1} + V_x \Delta t \quad (36)$$

$$Y_n = Y_{n-1} + V_y \Delta t \quad (37)$$

$$Z_n = Z_{n-1} + V_z \Delta t \quad (38)$$

From Figure 1, the relationships pertaining to the angles are:

$$\phi = \arcsin \frac{Z}{R_a} \quad (39)$$

$$\theta = \arctan \frac{Y}{X} \quad (40)$$

$$\delta = \arcsin \frac{\Delta R_a / \Delta t}{V_t} \text{ where } \Delta R_a / \Delta t = \text{average rate of change in altitude} \quad (41)$$

In spherical trigonometry, the law of cosines states:

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \quad (42)$$

The law of sines states:

$$\frac{\sin A}{\sin a} = \frac{\sin B}{\sin b} = \frac{\sin C}{\sin c} \quad (43)$$

where angles A, B, and C represent the angles of the spherical triangle on the earth's surface and a, b, and c represent the sides of the triangle and the angles subtended by them at earth's center. See Figure 2.

Now refer to Figure 3.

$$\cos \gamma = \cos \text{Co}\phi_o \cos \text{Co}\phi + \sin \text{Co}\phi_o \sin \text{Co}\phi \cos \Delta\theta \quad (44)$$

where

$$\Delta\theta = \theta - \theta_o \text{ and}$$

$$\text{Co}\phi_o = 90^\circ - \phi_o, \text{ then } \cos \text{Co}\phi_o = \sin \phi_o \text{ and } \sin \text{Co}\phi_o = \cos \phi_o$$

$$\text{Co}\phi = 90^\circ - \phi, \text{ then } \cos \text{Co}\phi = \sin \phi \text{ and } \sin \text{Co}\phi = \cos \phi$$

Equation (44) then becomes

$$\cos \gamma = \sin \phi_o \sin \phi + \cos \phi_o \cos \phi \cos \Delta\theta \quad (45)$$

$$\gamma = \arccos(\sin \phi_o \sin \phi + \cos \phi_o \cos \phi \cos \Delta\theta) \quad (46)$$

Then range =  $\gamma R$ ,  $\gamma$  is in radians. Earth's radius,  $R = 3440.239$  nautical miles.

$$\text{Range} = \gamma (3440.239) \quad (47)$$

Refer again to Figure 3.

$$\frac{\sin \sigma}{\sin \text{Co}\phi_o} = \frac{\sin \Delta\theta}{\sin \gamma} \quad \text{but } \sin \text{Co}\phi_o = \cos \phi_o \quad (48)$$

$$\sin \sigma = \frac{\cos \phi_o \sin \Delta\theta}{\sin \gamma} \quad (49)$$

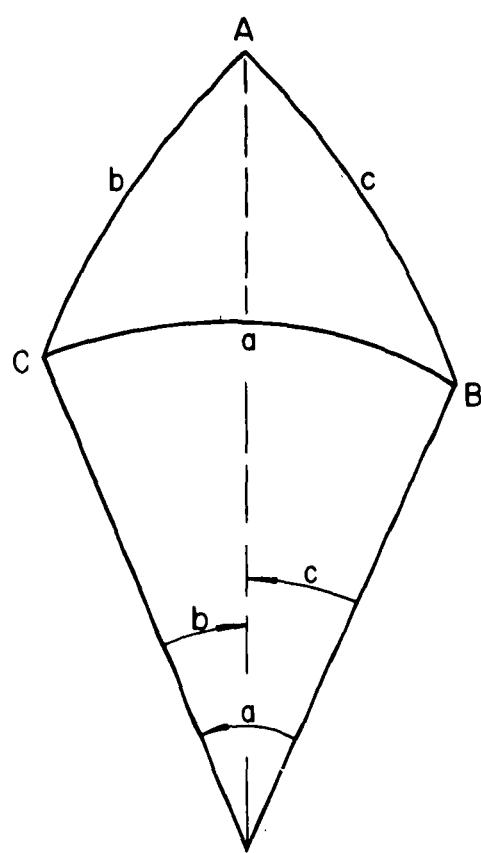

FIGURE 2

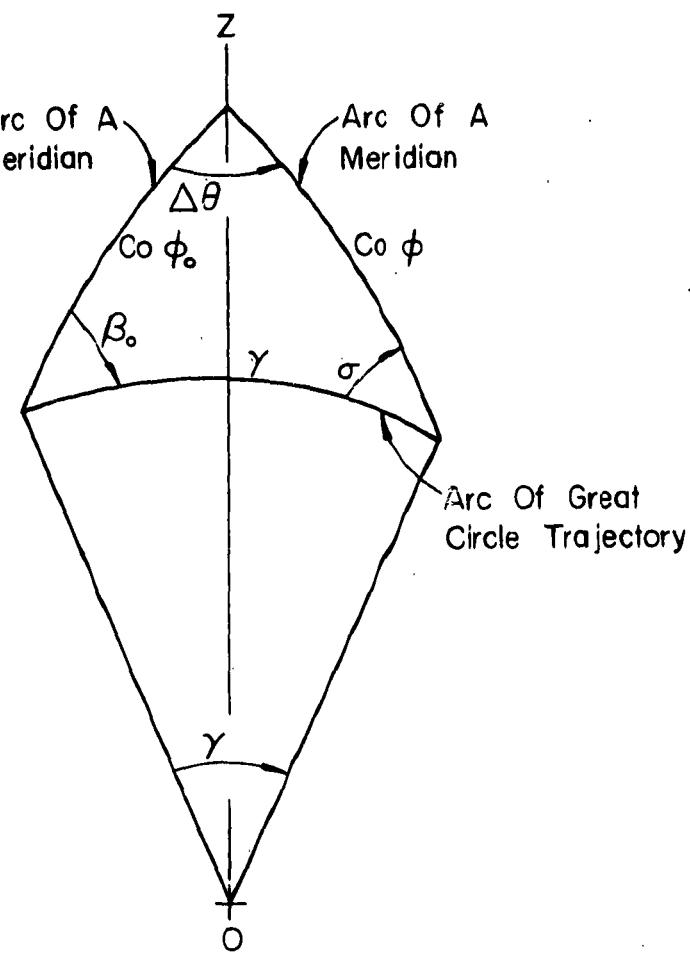

FIGURE 3

$$\sigma = \arcsin\left(\frac{\cos \phi_0 \sin \Delta\theta}{\sin \gamma}\right) \quad (50)$$

Sigma ( $\sigma$ ) is used to compute bearing ( $\beta$ ). In order to minimize the error caused by assuming that the trajectory follows an exact great circle (it would follow an exact great circle if the earth were not rotating), a smaller spherical triangle is used in the computer program.

Let symbols with subscript 1 stand for the next to last values computed. The symbols without subscripts stand for the newest values computed. Let  $\gamma_3$  equal the range increment angle.

Equation (46) now becomes:

$$\gamma_3 = \arccos\left[\sin \phi_1 \sin \phi + \cos \phi_1 \cos \phi \cos (\theta - \theta_1)\right] \quad (51)$$

Equation (50) becomes

$$\sigma = \arcsin\left(\frac{\cos \phi_1 \sin (\theta - \theta_1)}{\sin \gamma_3}\right) \quad (52)$$

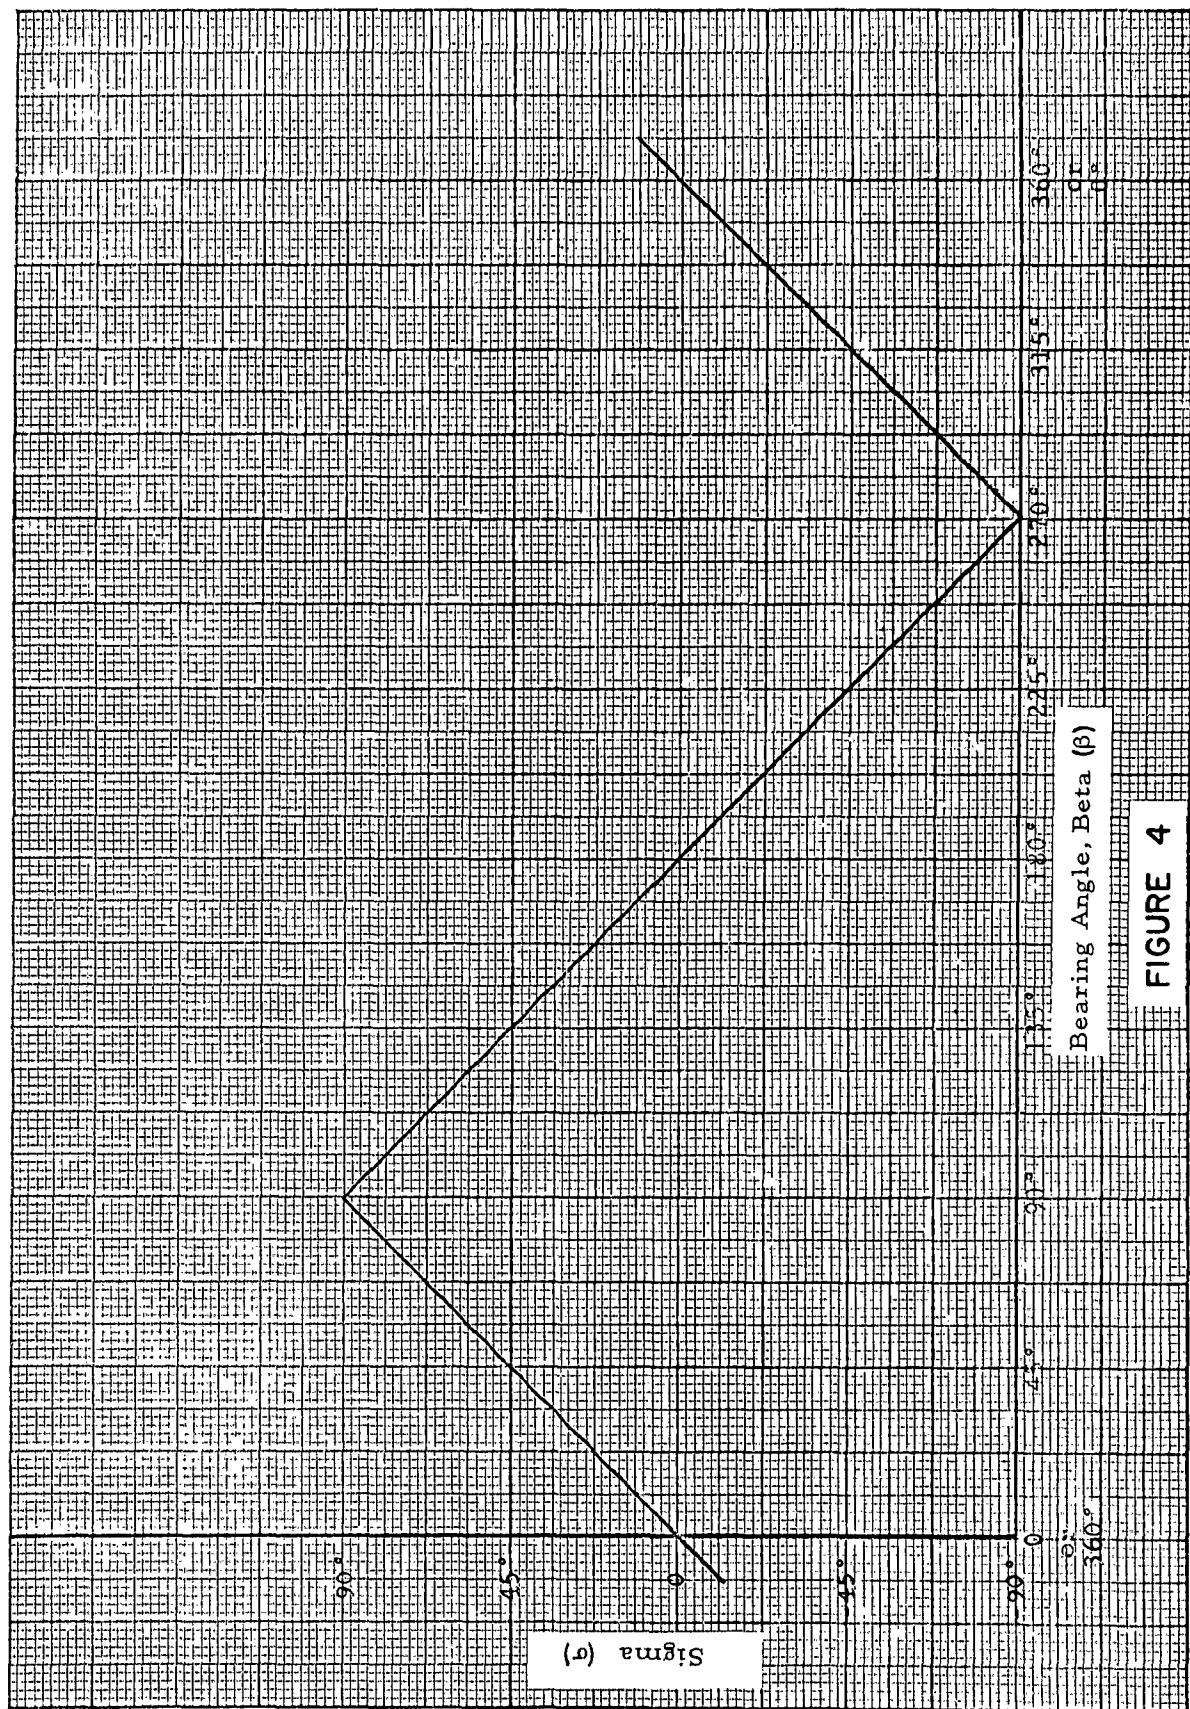

The computer uses the tangent function to determine the value of sigma ( $\sigma$ ). The value determined will lie between  $-90^\circ$  and  $+90^\circ$ . A graph showing sigma plotted against beta is shown in Figure 4.

From Figure 4 we can see that if beta is between  $0$  and  $90^\circ$

$$\beta = \sigma \quad (53)$$

If beta is between  $90^\circ$  and  $270^\circ$ ,

$$\beta = \pi - \sigma \quad (54)$$

**FIGURE 4**

If beta is greater than  $270^\circ$ ,

$$\beta = 2\pi + \sigma \quad (55)$$

The five equations (51) through (55) are integral parts of the computer program.

In order to compute  $A_t$ , which is the acceleration along the trajectory, let  $V_t$  = the last velocity computed along the trajectory,

$V_{t_1}$  = the next to last velocity computed along the trajectory

$\Delta t$  = the time increment being used the computer  
then

$$A_t = \frac{V_t - V_{t_1}}{\Delta t} \quad (56)$$

## DISCUSSION

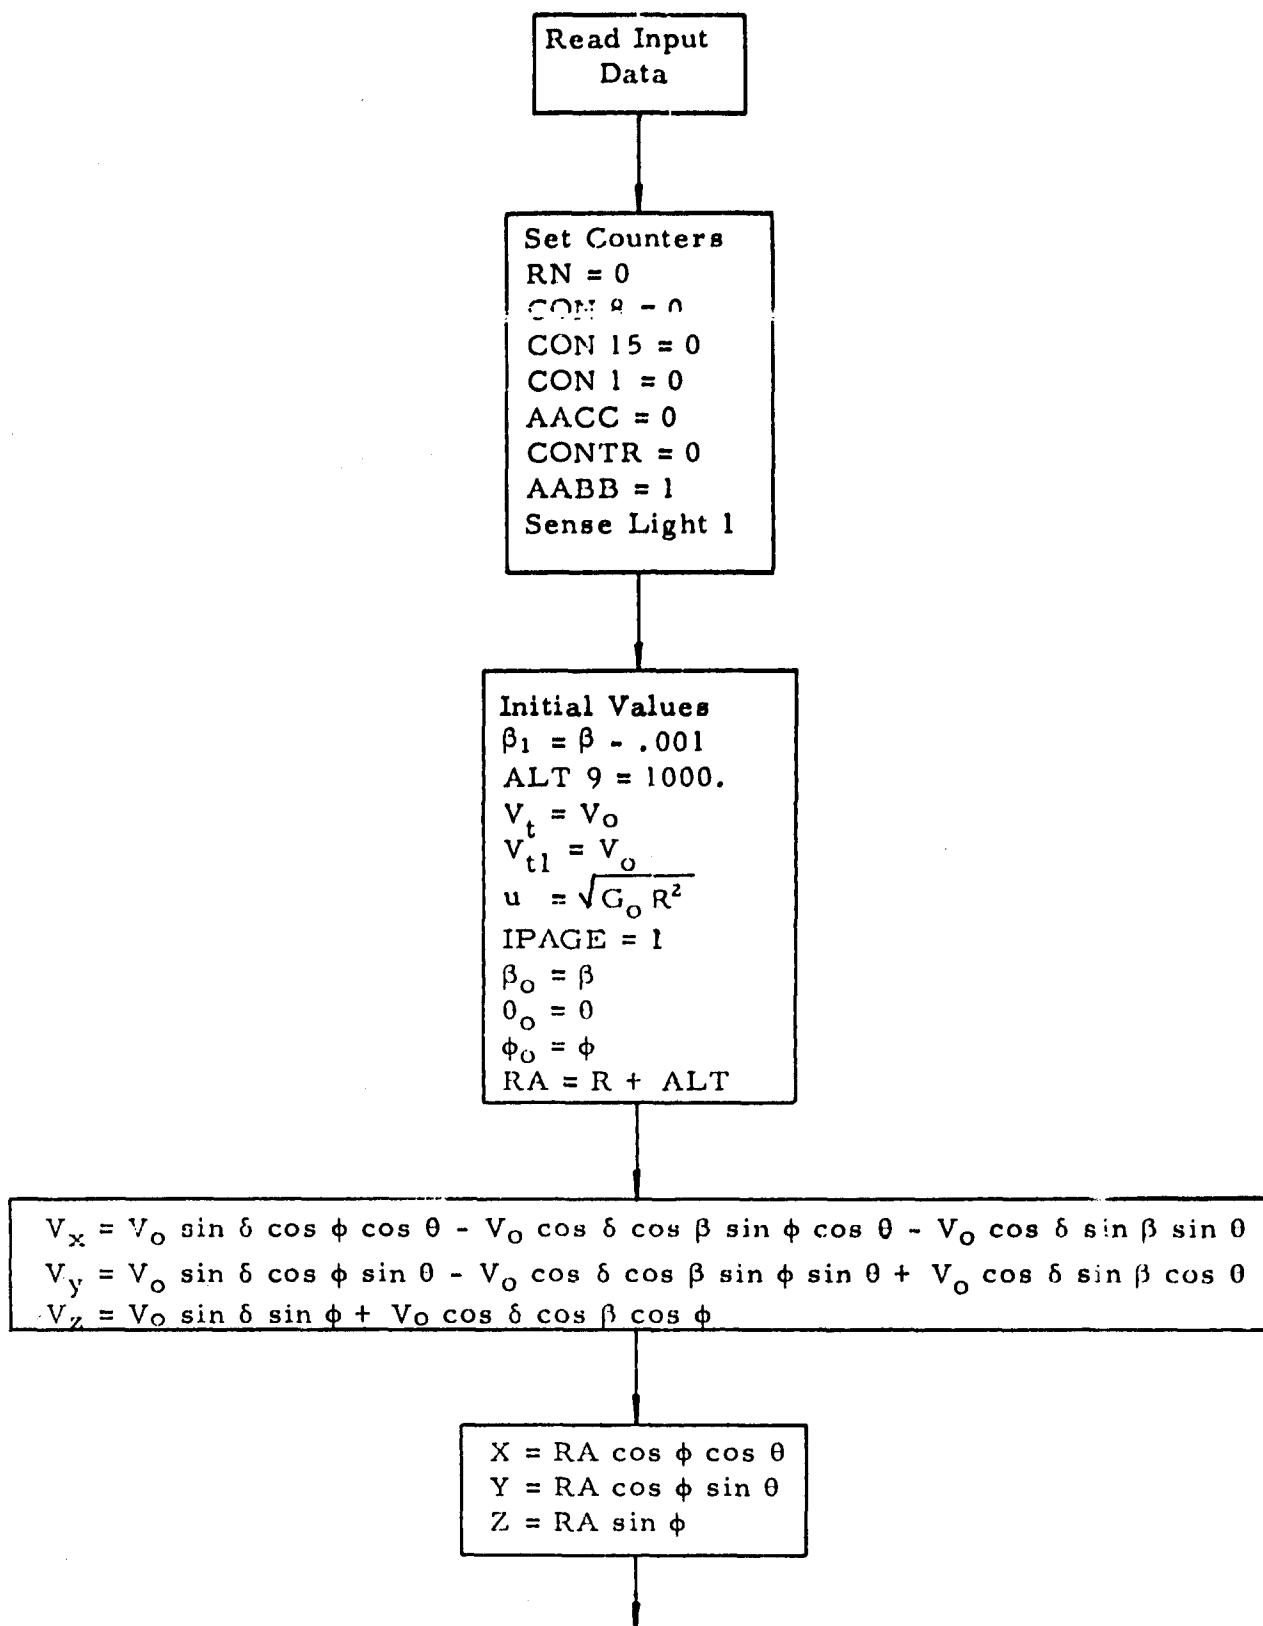

The computer program assumes a spherical earth and a point-mass.

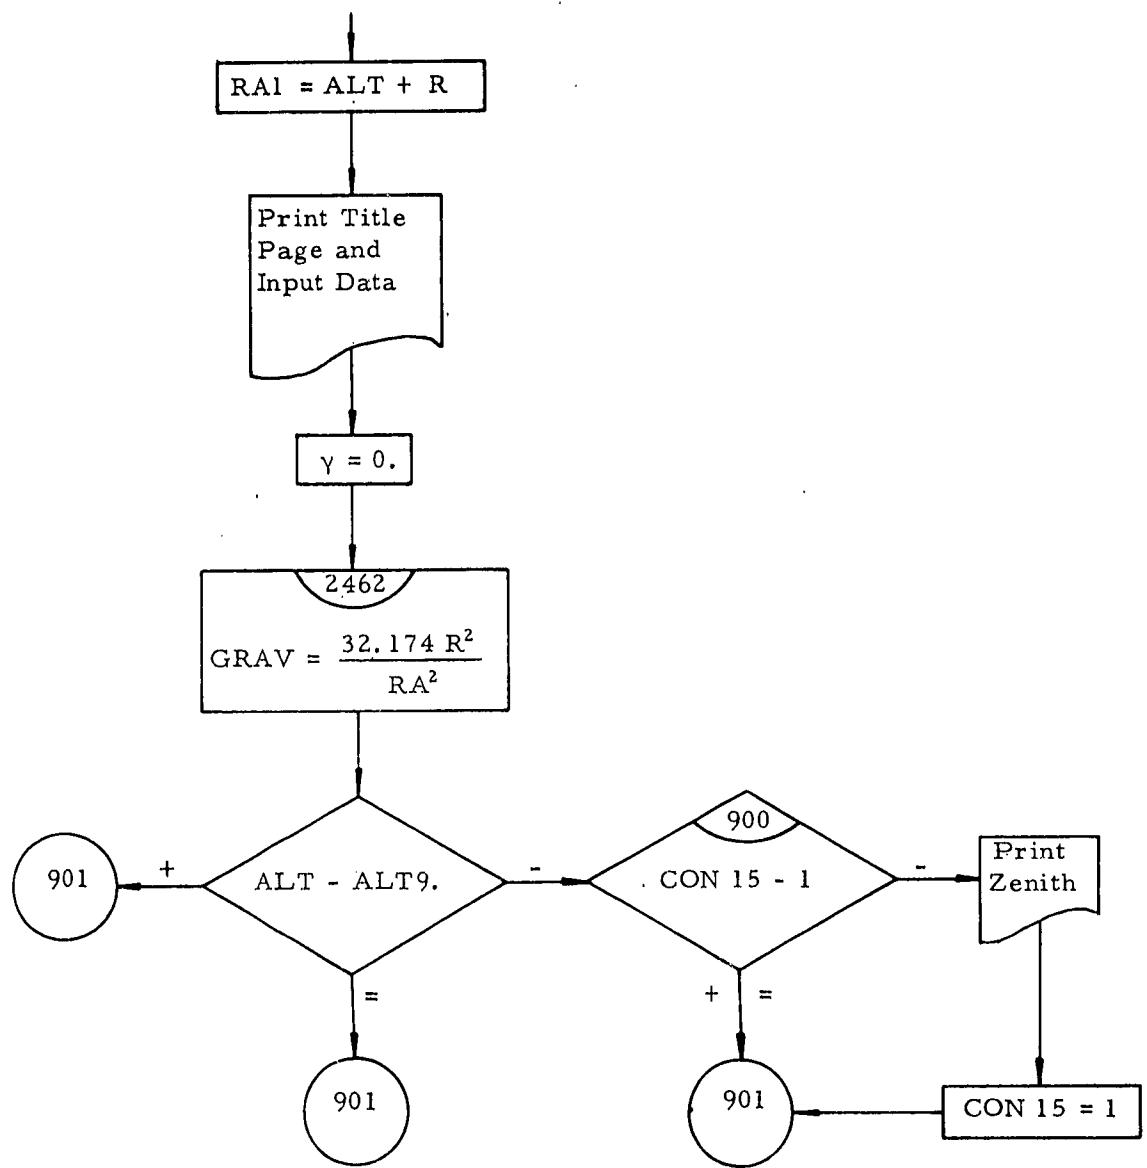

Other conditions are those which actually exist at earth's surface and at altitude from the surface.

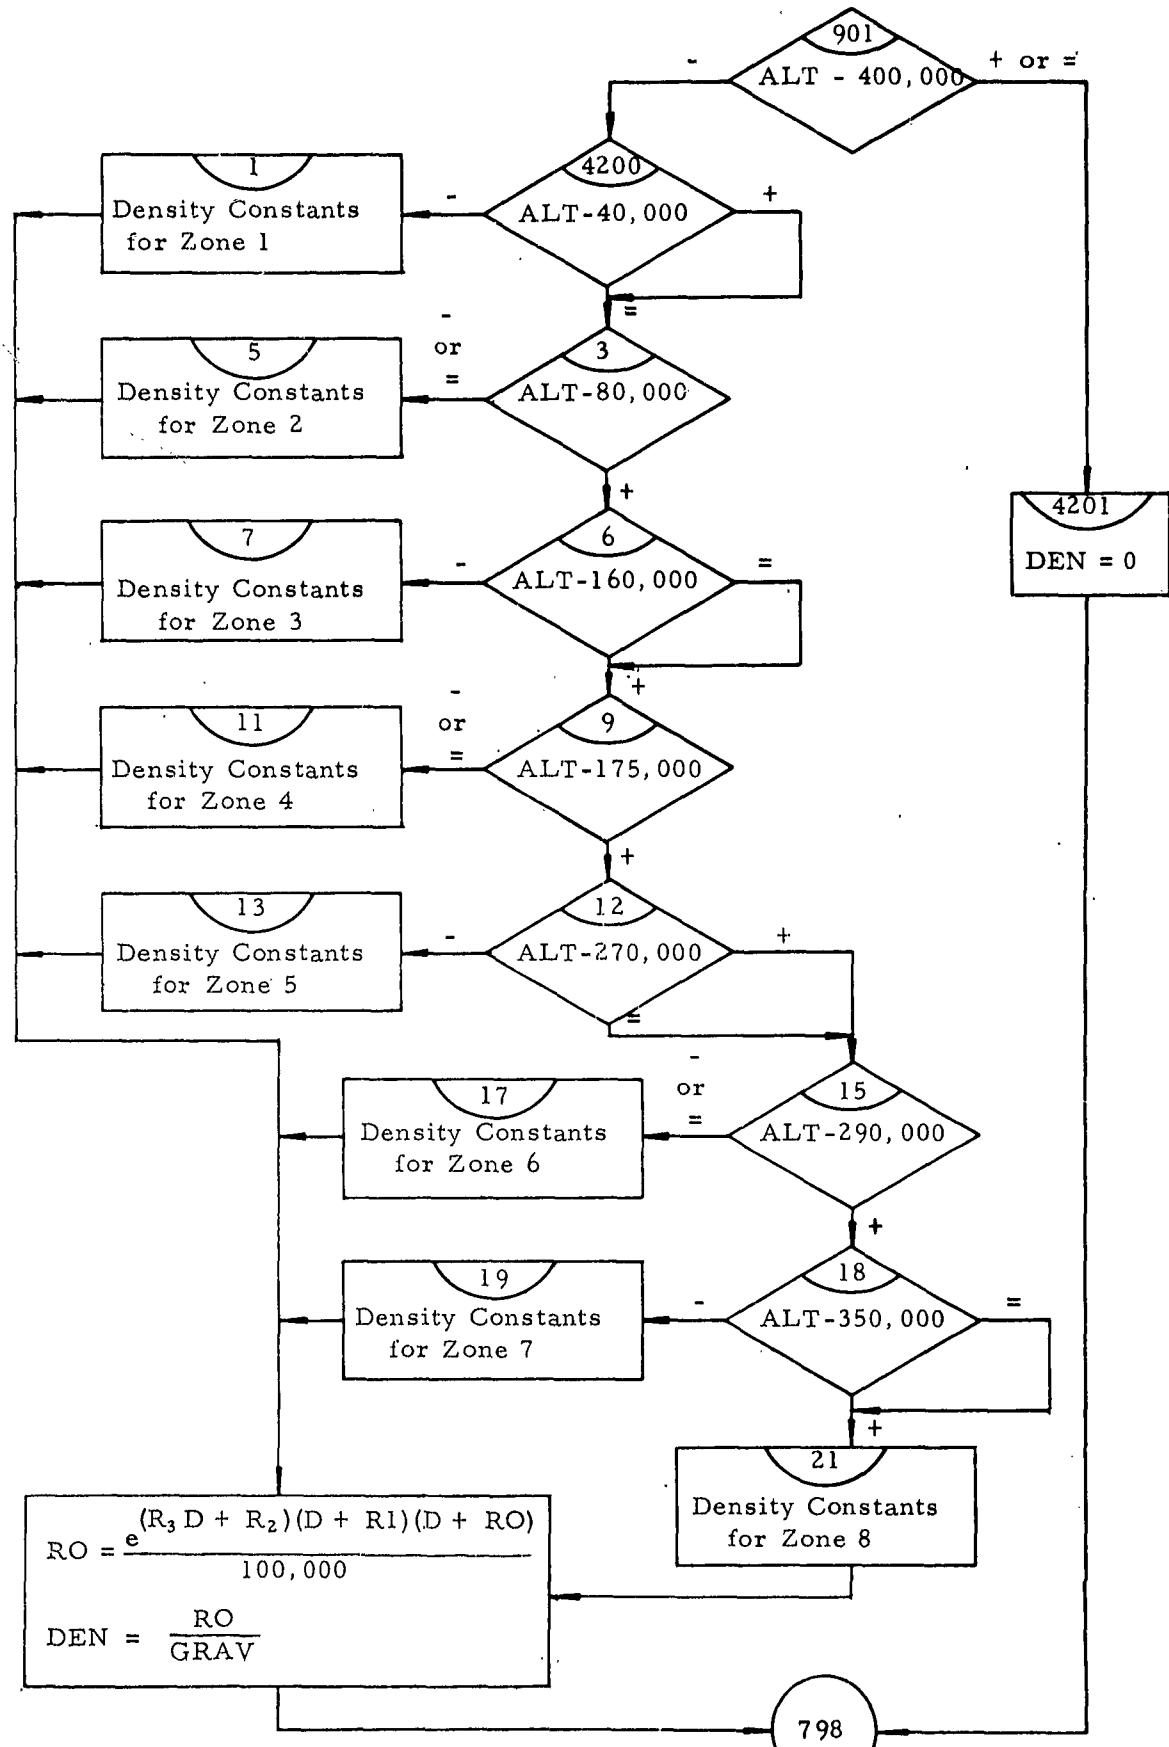

The time increment used by the computer is one second during the portion of the trajectory where conditions change slowly. During the re-entry portion of the trajectory when the altitude of the re-entry body is below 150,000 feet, the time increment is decreased to 0.1 second to increase accuracy. In order to give desired accuracy, this program was written in double precision. The program uses about 39,950 digits of memory. It is believed that this program produces highly accurate results.

For some of the angle relationships, it is assumed that the trajectory follows an exact great circle. The errors caused by this assumption are very small because of the short time increments used and the methods chosen to compute these relationships. These relationships are computer outputs and are not used to drive the computer.
